My Parents,

My Dear Sister and Brothers

ACKNOWLEDGMENTS

This piece of work will never be accomplished without our God Almighty with His blessings and who is able to do immeasurably more than we ask or imagine, according to His power that work within me.

I would like to express my sincere gratitude to my supervisor Prof. A. Safavi, for his patient guidance, constant support, encouragement and excellent advice throughout this study.

Deepest gratitude is also due to the members of the supervisory committee, Prof. A. Abbaspour, and Dr. J. Tashkhourian for their constructive comments on this thesis.

I would also like to thank my family for the support they provided me through my entire life without whose love, encouragement and editing assistance, I would not have finished this thesis.

Above all, I cannot express my full gratitude to Miss. Tohidi who without his guidance and persistence help this dissertation would not have been possible.

ABSTRACT

A novel silver nanocomposite electrode for amperometric determination of hydroxylamine and semicarbazide

by

Zahra Shojaeifard

A novel silver (Ag) nanocomposite electrode was proposed that fabricated from metal nanostructures and ionic liquids. The combined application of unique properties of nanomaterials and ionic liquids in the design of this Ag nanocomposite results in electrodes with interesting advantages compared to the conventional metal disk electrode.

In the first part of this thesis, the electrocatalytic effect of Ag paste nanocomposite electrode toward the oxidation of hydroxylamine in alkaline media was investigated.

Hydroxylamine was detected over a linear concentration range of 1 μ M- 5mM with double potential step chronoamperometry. The limit of detection was obtained as 0.30 μ M. This new method of hydroxylamine determination is reproducible, selective, and sensitive, and can be used for real sample analysis. The independency of the system from most of the interferences and its ability of easily removing the effect of most cationic interferences are the important features of this work.

In the second part, the Ag paste nanocomposite electrode was employed as an efficient electrocatalyst for semicarbazide oxidation in alkaline media.

The results confirm that this nanocomposite electrode has high sensitivity, low detection limit (0.6 μ M), wide linear range (1.3 μ M-0.5 mM and 0.5 mM- 2.3 mM), good long term stability and reproducibility for determination of semicarbazide.

Moreover, the electrode surface can be cleaned and renewed very easily by polishing on the smooth paper.

Therefore, this proposed electrode can have many applications as electrochemical sensors.

CONTENT	PAGE
CHAPTER ONE	
INTRODUCTION	1
1.1 Nanostructured materials	2
1.1.1 Synthesis of nanostructured materials.....	3
1.1.1.1 Ionic liquids	4
1.1.1.1.1 Fundamental aspects of ILs	5
1.1.1.1.2 Synthesis of nanostructures using ILs.....	6
1.1.1.1.3 Application of ILs in electrochemistry	7
1.1.1.2 Microwave assisted synthesis of nanomaterials.....	8
1.1.1.3 Microwave assisted synthesis of nanostructures using IL	9
1.2 Nanomaterials in electrochemistry.....	10
1.2.1 Nanocomposite electrodes	11
1.2.1.1 Metal composite electrodes.....	12
1.2.1.1.1 Ag composite electrodes	13
1.3 Electrochemical techniques	14
1.4 Analytes	14
1.4.1 Hydroxylamine.....	14
1.4.2 Semicarbazide	15
CHAPTER TWO	
LITERATURE REVIEW	18
2.1 Metal composite electrode	19
2.2 Electrocatalytic oxidation of hydroxylamine	20
2.3 Analytical determination of semicarbazide.....	22
2.4 Objective of the present work	24

CHAPTER THREE

EXPERIMENTAL SECTION..... 26

3.1	Determination of hydroxylamine and semicarbazide by Ag paste nanocomposite electrode.....	26
3.2	Materials	26
3.3	Synthesis of [n-octyl pyridinium] ⁺ PF ₆ ⁻ , (OPPF ₆)	26
3.4	Synthesis of Ag nanomaterials.....	27
3.5	Electrodes preparation.....	27
3.6	Apparatus	27

CHAPTER FOUR

RESULTS and DISCUSSION 29

4.1	Electrocatalytic oxidation of hydroxylamine at silver paste nanocomposite electrode.....	30
4.1.1	Fabrication of silver paste nanocomposite electrode	31
4.1.2	The performance of silver electrode toward hydroxylamine oxidation	34
4.1.3	Effect of scan rate	37
4.1.4	Amperometric determination of hydroxylamine at Ag paste nanocomposite electrode	37
4.1.5	Comparison of present sensor with previously reported sensors for hydroxylamine	51
4.1.6	Repeatability, reproducibility and stability of Ag paste nanocomposite electrode	53
4.1.7	Interference study.....	54
4.1.8	Real sample analyses	55
4.1.9	Conclusion	55

CHAPTER ONE

INTRODUCTION

1.1 Nanostructured materials

The world of nanotechnology is opening many new opportunities and challenges for science, technology, and society. Nanomaterials are designed at the molecular (nanometer) level to take advantage of their small size and have novel properties that are typically not observed in their conventional, bulk counterparts. Nanomaterials have a much larger surface area to volume ratio than their bulk counterparts, which is the basis of their novel physical and chemical properties exhibited by them.¹ Controlling the size, shape, monodispersity, yield of the desired size, as well as the shape and the various useful properties of nanomaterials with different chemistry have become a challenge for material chemists.² The ability to control the size, shape, and distribution of the metal nanoparticles and nanostructures provides great opportunities to investigate them for catalytic properties and to discover new applications in form of novel research techniques or consumer oriented medical devices and many things in between.^{2, 3, 4}

1.1.1 Synthesis of nanostructured materials

Nanoparticles can be prepared by physical and chemical methods. The physical methods, which frequently involve vapor deposition, depend on the principle of subdividing bulk precursors into nanoparticles. The chemical approaches involve reducing metal ions to metal atoms in the presence of stabilizers, followed by the controlled aggregation of atoms.⁵

Physico-chemical properties of metal nanoparticles for various applications strongly depend on their surface properties, in addition to the more commonly known size and shape effects. These surface properties of metal nanoparticles may vary significantly from one synthesis protocol to another, predominantly because concentration and type of stabilizing agents used in these synthesis methods can be quite different.⁶

In this approach, typically in the presence of a capping/stabilizing agent, metal ions are controllably reduced, wherein individual metal atoms combine to form metal nanoparticles stabilized by capping agents. Although in few instances reducing agents themselves act as stabilizers, capping agents are generally considered essential to minimize the surface free energy of metal nanoparticles, which would otherwise aggregate in the absence of these capping agents. Nanoscale particles of any material with a wide range of properties can be synthesized by employing various precursors such as polymers (poly vinylpyrrolidone), Br⁻, ionic liquid (IL) and etc.⁷

In most of the well established wet-chemistry routes of metal nanoparticles synthesis, aqueous or organic solvents are generally employed, while the use of ionic liquids (ILs) for synthesis of metal nanoparticles is a relatively recent phenomenon.⁸
